

The Metaphysics of Routley Star*

Edward N. Zalta
Philosophy Department
Stanford University

Abstract

This paper investigates two forms of the Routley star operation, one in Routley & Routley 1972 and the other in Leitgeb 2019. We use the background of object theory to define both forms of the Routley star operation and show how the basic principles governing both forms become derivable and need not be stipulated. Since no mathematics is assumed by our background formalism, the existence of the Routley star image s^* of a situation s is therefore guaranteed not by set theory but by a theory of abstract objects. The work in the paper integrates Routley star into a more general theory of (partial) situations that has previously been used to develop the theory of possible worlds and impossible worlds.

1 Introduction

The Routley ‘star’ operation was introduced in Routley & Routley 1972. Their study of the semantics of entailment assumed the existence of situations (‘set-ups’) that are neither consistent nor maximal (*ibid.*, 335–339).¹ In setting up the Routley star operator on situations, they used

*The research in this paper was first sketched for presentation in Hannes Leitgeb’s seminar *Logic and Metaphysics*, which was held at the Munich Center for Mathematical Philosophy in May 2022. I subsequently developed the results into a section of *Principia Logico-Metaphysica* (Zalta, m.s.). I’m indebted to Hannes Leitgeb, Uri Nodelman, Daniel Kirchner, Daniel West and Graham Priest for their comments about this material, all of which helped me to refine some of the results.

¹Some logicians use the term ‘non-normal worlds’ to describe situations that are neither maximal (complete) nor consistent. The Routleys, however, used the term ‘world’ for consistent and maximal situations (1972, 339). In what follows, we reserve the term

‘ H ’ to range over set-ups (i.e., “a class of propositions or wff”) and used ‘ A ’ to range over propositions or wffs (*ibid.*, 337). Then they considered the following condition (*ibid.*, 338) on the star (*) operation, which they label as (iv):

(iv) $\sim A$ is in H iff A is not in H^*

They subsequently stipulated that a set-up is \sim -normal if it satisfies (iv) for every A and $H = H^{**}$ (*ibid.*, 338).

That was then. Although the Routley star has subsequently been studied and applied in publications too numerous to mention, it was recently used in Leitgeb 2019 (321ff) to build a semantics for a system of hyperintensional logic (‘HYPE’). Leitgeb first builds a propositional language \mathcal{L} that includes propositional letters, with some standard logical connectives, but with a non-standard conditional. Leitgeb then constructs HYPE-models for \mathcal{L} in terms of structures whose elements include a non-empty set of states S and a valuation function V from S to the power set of the set of literals of the language \mathcal{L} , so that each state s in S is associated with a set of literals $V(s)$. I’ll describe HYPE models in fuller detail below, but for the purposes of this introduction, it is important to note that the various elements of HYPE models are simultaneously constrained by the requirements of a Routley star operation having the following properties, among others (Leitgeb 2019, 322):

- $V(s^*) = \{\bar{v} \mid v \in V(s)\}$
- $s^{**} = s$

Leitgeb then discusses the properties of the star operation and uses HYPE models to define various truth conditions for hyperintensional operators.

These two bookend cases, Routley & Routley 1972 and Leitgeb 2019, demonstrate how the Routley star operation has been deployed to help us understand various non-classical, but more fine-grained, semantic phenomena. But a look at the body of literature inclusive between these papers, a metaphysician would be hard-pressed to answer the question: What kind of metaphysics is represented by a semantics making use of Routley star, and how are we to understand the Routley star operation given that metaphysics?

‘world’ for maximal situations, some of which are possible worlds and some of which are impossible worlds.

Questions about the meaning of the Routley star operation were raised early on, in Copeland 1979 and van Benthem 1979. Restall 1999 (54) raises this question when he wrote:

The operator $*$ was introduced to relevant logic by Routley and Routley [23]. If $x \neq x^*$, then certainly we can get both $A \wedge \sim A \rightarrow B$ and $A \rightarrow B \vee \sim B$ to fail, but there is a price. The price is the obligation to explain the meaning of the operator $*$.

But even though we may now be more comfortable with Routley star and recognize how interesting and efficacious it is (after all the work that has been done), there is still an open question about what, exactly, is the proper metaphysical framework for defining and studying the Routley star operation.

In our two case studies, and for most studies in between, one typically finds the Routley star introduced into semantic models constructed with the help of set theory, domains of primitive entities (set-ups, situations, states, possible or impossible worlds), and functions defined on those domains, etc. Most authors don't spend time considering the metaphysics of the entities used in their semantic models, and quite rightly, given their goals. For their purposes, it is sufficient to adopt another attitude expressed in Restall 1999 (57):

It would be interesting to chart the connections between states as we have sketched them and other entities like ... objects, states of affairs, propositions, and many other things besides. However, this is neither the time nor the place for that kind of metaphysics. Suffice it to say that a coherent comprehensive view of states ought to tell us how these things fit together. For now, we will use *states* as the points in our frames for relevant logics.

For example, Leitgeb writes (2019, 323, footnote 9):

I want to leave open in this paper whether states are interpreted (i) in a metaphysically robust manner, or (ii) in a looser informational manner. In the first case, states would be “chunks of reality” that are “located in the world”, while in the second case they might be some kind of abstract entities corresponding to “pieces of thought”.

A notable exception is Mares 2004 (4.4–4.11), who produces an intuitive understanding of the background assumptions concerning properties,

states of affairs, situations, propositions, etc., that are used in the semantic models. But (a) the focus of Mares 2004 is to interpret the ternary relation R used in Routley-Meyer semantics for relevant logic (Routley & Meyer 1972, 1973), and (b) Mares assumes that some background theory of situations is available, such as Barwise and Perry 1983, for he takes a number of principles about situations as given.

By contrast, in what follows, we plan to address the metaphysical question without any mathematics, set theory, primitive domains of situations, states, or worlds (possible or impossible), or functions on domains. We won't identify propositions as sets of possible worlds, as functions from possible worlds to truth values, as sets of situations, or as classes of wffs. Nor will we assume any axioms governing primitive set-ups, situations, possible worlds, or impossible worlds. Instead, we shall *define* the Routley star operator metaphysically in a background ontology in which situations are defined and their first principles derived. And we employ a theory of propositions (= 0-ary relations) that is part of a larger, hyperintensional theory of n -ary relations – one on which necessarily equivalent relations and propositions aren't identified. We'll define a unique Routley star image s^* for each situation s . Our goal is to show that, in such a setting, (a) the metaphysical entities needed to formulate and understand the Routley star image can be defined and proved to exist, and (b) that the principles governing Routley star, as formulated in both Routley & Routley 1972 and Leitgeb 2019, can be *derived* rather than stipulated. It is *not* a goal of the paper to study non-classical negation; we'll use classical negation throughout. By systematizing the metaphysics of Routley star in the manner described below, we provide a precise understanding of the semantics of non-classical negation in terms of Routley star, in the way it was used in the papers that serve as the focus of our study.

1.1 The Background Theory

The background theory needed to do all this has been motivated and published elsewhere and we shall draw on those published results. In Zalta 1993 and 1997, *object theory*, henceforth OT, was deployed to study situations, possible worlds, and impossible worlds. In OT, a second mode of predication, x *encodes* F ($'xF'$), is added to second-order S5 quantified modal logic, and utilized in the following definitions:

- a *situation* is defined as an abstract object that encodes only properties of the form *being such that* p (i.e., properties of the form $[\lambda x p]$, where x is vacuously bound by the λ , and p is a variable ranging over propositions):

$$\text{Situation}(x) \equiv_{df} A!x \ \& \ \forall F(xF \rightarrow \exists p(F = [\lambda x p])) \quad (1)$$

- p is true in situation s ($s \models p$), or s makes p true, is defined as s encodes the propositional property *being such that* p :

$$s \models p \equiv_{df} s[\lambda x p] \quad (2)$$

(Henceforth, ' \models ' always takes the *smallest* scope; also, we may sometimes read $s \models p$ as s encodes p , thereby extending the notion of encoding.)

- a *possible world* is defined as a situation s that might be such that all and only true propositions are true in s :

$$\text{PossibleWorld}(s) \equiv_{df} \Diamond \forall p(s \models p \equiv p) \quad (3)$$

Given our convention, the subformula $s \models p \equiv p$ is to be parsed as $(s \models p) \equiv p$.

- an *impossible world* is defined as a maximal situation (that is, such that for every proposition p , either s makes p true or s makes the negation of p true) for which it is not possible that every proposition true in s is true:

$$\text{Maximal}(s) \equiv_{df} \forall p(s \models p \vee s \models \neg p) \quad (4)$$

$$\text{ImpossibleWorld}(s) \equiv_{df} \text{Maximal}(s) \ \& \ \neg \Diamond \forall p(s \models p \rightarrow p) \quad (5)$$

In Zalta 1993, it was shown that the basic principles of situation theory are derivable from the definition of *situation* given above (410–414). Indeed, 15 of the 19 principles outlined in Barwise 1989 were derived. And it was shown that the basic principles of possible world theory are derivable from the definition of *possible world* given above (414–419). These include formal versions of the following principles:

- every possible world is maximal, possible, and modally closed;
- there is a unique actual world;

- possibly p iff there is a possible world in which p is true; and
- necessarily p iff p is true in every possible world.

And in Zalta 1997 (646–649) it was shown that the basic principles of impossible world theory can be derived from the definition of *impossible world* given above. These include formal versions of:

- if it is not possible that p , then there exists a non-trivial impossible world in which p is true;²
- there exist impossible worlds where *ex contradictione quodlibet* fails; and
- there exist impossible worlds where disjunctive syllogism fails.

The above principles were all shown to be theorems. Familiarity with these results will be presupposed in what follows, since we now plan to *extend* and *build upon* them.

1.2 The Recent Developments We'll Need

The only recent developments of OT we'll need for the analysis of Routley star are the following definition and theorem schema:

$$\bar{p} \equiv_{df} \neg p \quad (6)$$

$$\vdash \exists s \forall p(s \models p \equiv \varphi), \text{ provided } s \text{ isn't free in } \varphi \quad (7)$$

Definition (6) lets us denote the negation of a proposition more simply as \bar{p} . As a theorem schema, (7) is in fact a comprehension schema for situations and is derivable from the comprehension schema for abstract objects, which asserts that for any condition φ with no free xs , there is an abstract object that encodes all and only the properties such that φ .³ A derivation of (7) is given in the Appendix. It is also important to note that it is provable that situations s and s' are identical just in case they make the same propositions true (Zalta 1993, 412):

²Cf. Nolan (1997, 542), who suggests that impossible worlds are governed by the comprehension principle: for every proposition that cannot be true, there is an impossible world where that proposition is true.

³Formally, this comprehension principle can be expressed as:

$$\exists x(A!x \ \& \ \forall F(xF \equiv \varphi)), \text{ provided } x \text{ isn't free in } \varphi$$

This was the key principle underlying the theorems in Zalta 1993 and 1997.

$$\vdash s = s' \equiv \forall p(s \models p \equiv s' \models p) \quad (8)$$

Consequently, it follows immediately from (7) that there is a unique situation that makes true all and only the propositions satisfying φ :

$$\vdash \exists! s \forall p(s \models p \equiv \varphi), \text{ provided } s \text{ isn't free in } \varphi \quad (9)$$

Moreover, it is a consequence of (9) that definite descriptions having the form $\iota x \forall p(s \models p \equiv \varphi)$ are always well-defined (i.e., provably have a denotation), provided s isn't free in φ . These are, therefore, *canonical* descriptions for situations.

Though canonical descriptions are always well-defined, one must take care when deploying them in a modal context, given that formal definite descriptions of the form $\iota x \varphi$ in OT rigidly denote the unique object, if there is one, that satisfies φ at the distinguished actual world. It is worth digressing a moment to understand the issues that arise and why the present paper will be able to ignore them. We conclude the digression and this section by formulating a theorem schema involving descriptions that will play an important role in the paper.

Note that in a modal logic with rigid definite descriptions, one can produce logical theorems that are not necessary. For example, the conditional $y = \iota x Gx \rightarrow Gy$ will be false at a world, say w_1 , when y (is assigned an object that) fails to be G at w_1 but is the unique G at the actual world w_0 (in such a case, the antecedent is true at w_1 but the consequent false at w_1). More generally, where φ_x^y is the result of substituting y for all the free occurrences of x in φ , the claim $y = \iota x \varphi \rightarrow \varphi_x^y$ is not a necessary truth, though it is logically true (i.e., true at the distinguished actual world of every model, for every assignment to x) given the semantics of rigid definite descriptions.

In a fuller presentation of OT, we could axiomatize rigid definite descriptions by introducing an actuality operator \mathcal{A} and asserting, as an axiom:

$$y = \iota x \varphi \equiv \forall x(\mathcal{A}\varphi \equiv x = y) \quad (10)$$

This is a form of the Hintikka principle (1959); it is a necessary truth and it immediately implies the following as a necessary truth, in which $\mathcal{A}\varphi_x^y = (\mathcal{A}\varphi)_x^y = \mathcal{A}(\varphi_x^y)$:

$$\vdash y = \iota x \varphi \rightarrow \mathcal{A}\varphi_x^y, \text{ provided } y \text{ is substitutable for } x \text{ in } \varphi \quad (11)$$

If we then adjust the original example, it should be easy to see that $y = \iota x Gx \rightarrow \mathcal{A}Gy$ is a necessary truth. But though (10), (11), and their instances are necessary truths, the axiomatization of the actuality operator includes an axiom, namely $\mathcal{A}\varphi \rightarrow \varphi$, that is a logical truth which isn't necessary (Zalta 1988).⁴ So the Rule of Necessitation has to be slightly adjusted; one may not apply the rule to necessitate a theorem whose proof depends on the axiom $\mathcal{A}\varphi \rightarrow \varphi$.

In what follows, though, we won't need to worry about illicit applications of the Rule of Necessitation since all of the definite descriptions we'll deploy involve a special class of formulas for which we can derive the conditional $y = \iota x \varphi \rightarrow \varphi_x^y$ without appealing to the contingent axiom for actuality. The formulas in question are *modally collapsed*, i.e., any formula φ for which it is provable that $\Box(\varphi \rightarrow \Box\varphi)$. When a formula having this form is provable, one can prove $\mathcal{A}\varphi \equiv \varphi$ without appealing to the contingent axiom $\mathcal{A}\varphi \rightarrow \varphi$.⁵ If φ is modally collapsed, then $y = \iota x \varphi \rightarrow \varphi_x^y$ is a necessary truth:

$$\vdash y = \iota x \varphi \rightarrow \varphi_x^y, \quad (12)$$

provided φ is modally collapsed and y is substitutable for x in φ

(See the Appendix for the proof.) In this paper, we shall appeal only to definite descriptions in which the matrix is modally collapsed, and so we won't need to worry about mistakenly applying the Rule of Necessitation to theorems derived from a logical truth that is not necessary.

In particular, we have, as a special case of (12), that when φ is modally collapsed, then if a situation s is identical to the situation that makes true all and only the propositions satisfying φ , then s makes true all and only the propositions satisfying φ , i.e.,

⁴To see why the formula schema $\mathcal{A}\varphi \rightarrow \varphi$ can't be necessitated, note that the conditional is true at the actual world: if φ is true at the actual world, then the conditional is true at the actual world (by truth of the consequent), and if φ is false at the actual world, then the conditional is true at the actual world (by failure of the antecedent). However, the conditional is false at any world w_1 whenever φ is true at the actual world but false at w_1 .

⁵Assume $\Box(\varphi \rightarrow \Box\varphi)$. Then by the $K\Box$ principle, i.e., $\Box(\psi \rightarrow \chi) \rightarrow (\Box\psi \rightarrow \Box\chi)$, it follows that $\Box\varphi \rightarrow \Box\Box\varphi$. But in S5, $\Box\Box\varphi \rightarrow \Box\varphi$. So by hypothetical syllogism, we've established:

$$(\theta) \quad \Box\varphi \rightarrow \Box\varphi$$

Now to see that $\mathcal{A}\varphi \equiv \varphi$, we prove both directions. (\rightarrow) Assume $\mathcal{A}\varphi$. Then $\Box\varphi$. So by (θ), $\Box\varphi$. Hence φ , by the T schema. (\leftarrow) Assume φ . Then $\Box\varphi$. But again by (θ), it follows that $\Box\varphi$. Hence $\mathcal{A}\varphi$.

$$\vdash s = \iota s' \forall p (s' \models p \equiv \varphi) \rightarrow \forall p (s \models p \equiv \varphi), \quad (13)$$

provided s' isn't free in φ and φ is modally collapsed

The keys to the proof in the Appendix are the facts that $s' \models p$ is, by definition (2), an instance of the formula xF and that the modal logic of encoding is $xF \rightarrow \Box xF$. So by the Rule of Necessitation, $\Box(xF \rightarrow \Box xF)$ and, as an instance, $\Box(s' \models p \rightarrow \Box s' \models p)$. This fact, and the fact that φ is modally collapsed, lets us validly infer that the formula $\forall p (s' \models p \equiv \varphi)$ is modally collapsed. So the description $\iota s' \forall p (s' \models p \equiv \varphi)$ will be governed by (12).

(13) plays a crucial role in what follows. All of descriptions of the form $\iota s' \forall p (s' \models p \equiv \varphi)$ used in the present work will be constructed in terms of formulas φ that are modally collapsed; it is provable that their truth necessarily implies their own necessity. This should forestall any concerns about the fact that we shall be working within a modal context in which definite descriptions are interpreted rigidly.

2 Definitions and Theorems

For any situation s , we define *the Routley star image of s* , written s^* , as the situation s' that makes true all and only those propositions having negations that fail to be true in s :

$$s^* =_{df} \iota s' \forall p (s' \models p \equiv \neg s \models \bar{p}) \quad (14)$$

Clearly, the definiens has a denotation, since it is a canonical description (s' doesn't occur free in $\neg s \models \bar{p}$). So s^* is well-defined. Since it can be shown that $\neg s \models \bar{p}$ is a modally collapsed formula, it follows from (14) by (13) that p is true in s^* iff \bar{p} fails to be true in s :

$$\vdash \forall p (s^* \models p \equiv \neg s \models \bar{p}) \quad (15)$$

This holds for any situation s . (The first part of the proof in the Appendix establishes that $\neg s \models \bar{p}$ is a modally collapsed formula.)

We now establish a number of facts that show (14) and theorem (15) properly capture the definition of s^* in Routley & Routley 1972. Since formulas of the form $\varphi \equiv \neg\psi$ are necessarily equivalent to formulas of the form $\neg\varphi \equiv \psi$, (15) implies that, for any proposition p , \bar{p} is true in s if and only if p fails to be true in s^* :

$$\vdash \forall p (s \models \bar{p} \equiv \neg s^* \models p) \quad (16)$$

Again, this holds for any situation s . (16) is an analogue of the Routleys' principle (iv), as formulated in the opening paragraph of Section 1 above.

To set up the next confirmation that (14) is correct, let us say that s *has a glut with respect to p* , written $GlutOn(s, p)$, if and only if both p and \bar{p} are true in s ; and that s *has a gap with respect to p* , written $GapOn(s, p)$, if and only if neither p nor \bar{p} is true in s :

$$GlutOn(s, p) \equiv_{df} s \models p \ \& \ s \models \bar{p} \quad (17)$$

$$GapOn(s, p) \equiv_{df} \neg s \models p \ \& \ \neg s \models \bar{p} \quad (18)$$

Then it follows that the condition $s = s^{**}$ implies that if s has a glut with respect to p , then s^* has a gap with respect to p :

$$\vdash s = s^{**} \rightarrow (GlutOn(s, p) \rightarrow GapOn(s^*, p)) \quad (19)$$

And $s = s^{**}$ also implies that if $s = s^{**}$, then if s has a gap with respect to p , then s^* has a glut with respect to p :

$$\vdash s = s^{**} \rightarrow (GapOn(s, p) \rightarrow GlutOn(s^*, p)) \quad (20)$$

Moreover, it can be shown, without the assumption that $s = s^{**}$, that if s neither has a glut nor a gap w.r.t. p , then s^* makes p true if and only if s makes p true:

$$\vdash (\neg GlutOn(s, p) \ \& \ \neg GapOn(s, p)) \rightarrow (s^* \models p \equiv s \models p) \quad (21)$$

It then follows that if, for every proposition p , s neither has a glut nor a gap w.r.t. p , then $s^* = s$ (since they make the same propositions true); and for every proposition p , s neither has a glut nor a gap w.r.t. p if and only if for every proposition p , s makes p true if and only if s fails to make \bar{p} true:

$$\vdash \forall p (\neg GlutOn(s, p) \ \& \ \neg GapOn(s, p)) \rightarrow s^* = s \quad (22)$$

$$\vdash \forall p (\neg GlutOn(s, p) \ \& \ \neg GapOn(s, p)) \equiv \forall p (s \models p \equiv \neg s \models \bar{p}) \quad (23)$$

Intuitively, (23) tells us that if s is free of gluts and gaps, then it is coherent with respect to negation.

We conclude this section by deriving three interesting facts, the first two of which require us to definition *the null situation* (s_\emptyset), in which no propositions are true, and *the trivial situation* (s_V), in which every proposition is true:

$$s_{\emptyset} =_{df} \lambda s' \forall p (s' \models p \equiv p \neq p) \quad (24)$$

$$s_V =_{df} \lambda s' \forall p (s' \models p \equiv p \equiv p) \quad (25)$$

The facts are that: if $s^{**} = s$ holds universally, then the Routley star image of the null situation is the trivial situation; if $s^{**} = s$ holds universally, then the Routley star image of the trivial situation is the null situation; and s^{**} is identical to s if and only if, for every proposition p , p is true in s iff $\bar{\bar{p}}$ is true in s :

$$\vdash \forall s (s^{**} = s) \rightarrow s_{\emptyset}^* = s_V \quad (26)$$

$$\vdash \forall s (s^{**} = s) \rightarrow s_V^* = s_{\emptyset} \quad (27)$$

$$\vdash s^{**} = s \equiv \forall p (s \models p \equiv s \models \bar{\bar{p}}) \quad (28)$$

(28) becomes interesting when we consider the passage in Routley & Routley 1972 (338) in which they discuss their principle (iv) (noted above in the preamble to this section):

Requirement (iv) on its own does not suffice for the normality of the negation, since it does not assume such characteristic negation features as double negation features. For these features it is, however, unnecessary to adopt the over-restrictive condition $H = H^*$, which would take us back to (ii); it suffices to require that $H = H^{**}$.

The Routleys don't say here exactly which double negation features they are referring to. But (28) tells us that the condition $s^{**} = s$ is equivalent to a specific double negation feature. As we've seen, the Routleys go on to suggest that a 'set-up', i.e., a situation s , is classical ('normal') w.r.t. double negation when $s^{**} = s$. Even if the fact expressed by (28) has been made explicit in the literature, it has now been derived from general principles that don't assume any mathematics, in a system in which propositions have been axiomatized, and situations and their Routley star images have been defined, in purely logical and metaphysical terms.⁶

⁶See Punčochář & Sedlár 2022 for a discussion of the Routley star operation in information-based semantics rather than truth-conditional semantics, and Odintsov & Wansing 2020 for a comparison of the hyperintensional propositional logic in HYPE with a number of other logics.

3 An Alternative Definition

In Section 5 below, we investigate a variant definition of the Routley star image, in which s^* is defined as the situation that makes true all and only the negations of propositions that fail to be true in s :

$$s^* =_{df} \lambda s' \forall p (s' \models p \equiv \exists q (\neg s \models q \ \& \ p = \bar{q})) \quad (\vartheta)$$

Since the conditions $s \models p$ and $p = \bar{q}$ are modally collapsed, the condition $\exists q (\neg s \models q \ \& \ p = \bar{q})$ is as well.⁷ So (ϑ) immediately implies, by (13):

$$\forall p (s^* \models p \equiv \exists q (\neg s \models q \ \& \ p = \bar{q})) \quad (\xi)$$

(ϑ) and (ξ) are of interest because the key condition $\exists q (\neg s \models q \ \& \ p = \bar{q})$ is *not* equivalent to the condition $\neg s \models \bar{p}$ used in (14).⁸ To see why, consider a simple situation, say s , in which a single proposition, say p_1 , is true. Let's ignore all other propositions and consider what propositions are true in s^* according to (15) vs. what propositions are true s^* according to (ξ) . According to (15), the following propositions are true in s^* :

- p_1 (since $\neg s \models \bar{p}_1$),
- \bar{p}_1 (since $\neg s \models \bar{\bar{p}}_1$),
- $\bar{\bar{p}}_1$ (since $\neg s \models \bar{\bar{\bar{p}}}_1$),
- and so on.

⁷In OT, $p = q$ is defined as the property identity $[\lambda x p] = [\lambda x q]$ (Zalta 1993, 409), where the identity of properties $F = G$ is defined as $\Box \forall x (x \models F \equiv x \models G)$ (*ibid.*, 407). Given the S4 axiom then, it is easy to show $F = G \rightarrow \Box F = G$. So by the Rule of Necessitation $\Box(F = G \rightarrow \Box F = G)$. Instantiating F and G to $[\lambda x p]$ and $[\lambda x q]$ and applying the definition of identity for propositions, we have the instance $\Box(p = q \rightarrow \Box p = q)$, which holds for any propositions p and q . Hence $\Box(p = \bar{q} \rightarrow \Box p = \bar{q})$. And if φ and ψ are modally collapsed, it follows that $\varphi \ \& \ \psi$ is modally collapsed. From these facts it doesn't take much more work to show $\Box(\exists q (\neg s \models q \ \& \ p = \bar{q}) \rightarrow \Box \exists q (\neg s \models q \ \& \ p = \bar{q}))$.

⁸In what follows, it is important to distinguish the following two conditions:

- (1) $\exists q (\neg s \models q \ \& \ p = \bar{q})$
- (2) $\exists q (\neg s \models q \ \& \ q = \bar{p})$

Condition (2) is equivalent to $\neg s \models \bar{p}$, by the following argument:

(\rightarrow) Assume $\exists q (\neg s \models q \ \& \ q = \bar{p})$ and suppose r is such a propositions, so that we know both $\neg s \models r$ and $r = \bar{p}$. Then $\neg s \models \bar{p}$. (\leftarrow) Assume $\neg s \models \bar{p}$. Then $\neg s \models \bar{p} \ \& \ \bar{p} = \bar{p}$, by the reflexivity of identity and &I. Hence, $\exists q (\neg s \models q \ \& \ q = \bar{p})$.

But we're now going to focus on condition (1), to see why it isn't equivalent to $\neg s \models \bar{p}$.

But according to (ξ) , neither p_1 nor $\overline{p_1}$ are true in s^* (neither p_1 nor $\overline{p_1}$ is the negation of a proposition that s fails to encode). Instead, the following propositions are true in s_1 according to (ξ) :

- $\overline{\overline{p_1}}$ (since $\neg s \models \overline{p_1}$ and $\overline{\overline{p_1}}$ is the negation of $\overline{p_1}$),
- $\overline{\overline{\overline{p_1}}}$ (since $\neg s \models \overline{\overline{p_1}}$ and $\overline{\overline{\overline{p_1}}}$ is the negation of $\overline{\overline{p_1}}$),
- and so on.

Interestingly, however, the conditions $\exists q(\neg s \models q \ \& \ p = \overline{q})$ and $\neg s \models \overline{p}$ are equivalent under the assumption that propositions are identical to their double negations, i.e., under the assumption that:

$$\forall p(\overline{\overline{p}} = p) \quad (\zeta)$$

To see this, note how (ζ) plays a role in the proof of both directions of the biconditional asserting the equivalence:

$$\exists q(\neg s \models q \ \& \ p = \overline{q}) \equiv \neg s \models \overline{p} \quad (\omega)$$

Proof: (\rightarrow) Assume $\exists q(\neg s \models q \ \& \ p = \overline{q})$ and let r be such a proposition, so that we know both $\neg s \models r$ and $p = \overline{r}$. The latter implies that $\overline{p} = \overline{\overline{r}}$, for if propositions are identical, so are their negations. But by (ζ) , $\overline{\overline{r}} = r$. Hence, $\overline{p} = r$ and so $\neg s \models \overline{p}$. (\leftarrow) Assume $\neg s \models \overline{p}$. Then by (ζ) , $\neg s \models \overline{p} \ \& \ p = \overline{\overline{p}}$. By existentially generalizing on \overline{p} we have: $\exists q(\neg s \models q \ \& \ p = \overline{q})$. \bowtie

Of course, OT doesn't imply (ζ) since the identity conditions of relations and propositions are hyperintensional; one may consistently claim that propositions and their double negations are distinct despite being necessarily equivalent. That's because in OT, propositions p and q are identical just in case the corresponding propositional properties $[\lambda x p]$ and $[\lambda x q]$ are identical, as explained in footnote 7. Property identity is, in turn, defined in terms of being necessarily encoded by the same objects, not in terms of being necessarily exemplified by the same objects. Consequently, necessarily equivalent properties and propositions are not identified; properties and propositions are more fine-grained.

So one can't simply replace the definiens of (14) with the definiens:

$$is' \forall p(s' \models p \equiv \exists q(\neg s \models q \ \& \ p = \overline{q}))$$

This won't preserve the results we've established thus far. But we could define a group of propositions that are identical with their double negations, and in the next section, we investigate the Routley star image s^* of situations s that are constructed out of such propositions.

4 HYPE

Leitgeb (2019, 321ff) builds a semantics for a system of hyperintensional propositional logic ('HYPE'). He first builds a propositional language \mathcal{L} by starting with atomic propositional letters p_1, p_2, \dots , and logical symbols $\neg, \wedge, \vee, \rightarrow$, and \top (where \rightarrow does not express the material conditional). He writes $\overline{p_i}$ for $\neg p_i$, and uses $\overline{\overline{p_i}}$ as an abbreviation for p_i . The proposition letters and their negations constitute the *literals*. Leitgeb then constructs HYPE-models for \mathcal{L} in terms of structures $\langle S, V, \circ, \perp \rangle$, where the elements of the models are simultaneously constrained by the requirements of a Routley star operation $*$. He describes the elements of the models as follows (Leitgeb 2019, 321–22):

- S is a non-empty set of states.
- V is a function (the valuation function) from S to the power set of the set of literals of the language \mathcal{L} , so that each state s in S is associated with a set of literals $V(s)$.
- \circ is a partial fusion function on states that is idempotent and, when defined, commutative and partially associative.
- \perp is a relation of incompatibility that relates states s and s' when some proposition p is true at one and its negation \overline{p} is true at the other.

The Routley star operation that constrains these models will be discussed and defined later, in Section 5.

Consequently, in the remainder of this paper, we use OT to reconstruct the above elements of HYPE models and we'll see that the reconstruction comports with both of the suggestions for understanding HYPE states quoted above in Leitgeb 2019 (323, footnote 9). In Section 4.1 we develop basic definitions and show how to interpret the HYPE V function; in Section 4.2 we show how to interpret the HYPE fusion operation \circ ; and in Section 4.3, we show how to interpret the HYPE

incompatibility relation \perp . Finally, in Section 5, we define the HYPE version of Routley star and prove that it has the expected features.

4.1 HYPE Propositions and HYPE States

First, we work our way towards a definition of a *Hype*-state by defining *Hype*-propositions. We say that (29) a *Hype*-proposition is any proposition p that is identical to its double negation:

$$\text{Hype}(p) \equiv_{df} \bar{\bar{p}} = p \quad (29)$$

Clearly, then it follows that (30) if p is a *Hype*-proposition, then so is its negation \bar{p} :

$$\vdash \text{Hype}(p) \rightarrow \text{Hype}(\bar{p}) \quad (30)$$

Though OT guarantees the existence of propositions (by 0-ary relation comprehension) and provides identity conditions for them (footnote 7), it doesn't guarantee the existence of *Hype*-propositions. The identity conditions for propositions in OT leave one free to assert the existence of *Hype*-propositions and the existence of propositions that are more fine-grained, e.g., by asserting $\exists p(\bar{\bar{p}} \neq p)$. Though $\Box(\bar{\bar{p}} \equiv p)$ is a theorem, it doesn't follow that $\bar{\bar{p}} = p$.

Consequently, for the remainder of this section, let us work under the assumption that there are *Hype*-propositions:

$$\textbf{Assumption: } \exists p \text{Hype}(p) \quad (31)$$

Now we may define x is a *HypeState* just in case x is a situation such that every proposition true in x is a *Hype*-proposition:

$$\text{HypeState}(x) \equiv_{df} \text{Situation}(x) \ \& \ \forall p(x \models p \rightarrow \text{Hype}(p)) \quad (32)$$

So we're identifying *HypeStates* not as primitive entities but as situations. Thus when Leitgeb speaks of the members of $V(s)$ as the facts or states of affairs obtaining at s (2019, 322), we may interpret this in terms of our defined notion, p is true in s , as follows:

$$\bullet \ p \in V(s) \equiv_{df} s \models p$$

Now it is easy to prove the existence of *HypeStates*; (31) guarantees there are *Hype*-propositions and (7) guarantees that for any condition on *Hype*-propositions, there are situations that make true all and only such propositions. Clearly, any such situation is a *HypeState*.

Indeed, we now derive, from (7), comprehension conditions for *HypeStates* with the help of some new variables. Note that the conditions $\text{Hype}(p)$ and $\text{HypeState}(x)$, defined respectively in (29) and (32), are modally collapsed conditions. So may use introduce restricted variables to range over them. For clarity, we use a special new variables in a distinguished, new font:

- p, q, \dots are restricted variables ranging over *Hype*-propositions.
- s, s', \dots be are restricted variables ranging over *HypeStates*.

Using these variables we may formulate Simplified Comprehension for *HypeStates* as follows:

$$\vdash \exists s \forall p (s \models p \equiv \varphi), \text{ provided } s \text{ isn't free in } \varphi \quad (33)$$

Clearly, in the usual way, it is provable that there is a unique such *HypeState* for each such instance:

$$\vdash \exists! s \forall p (s \models p \equiv \varphi), \text{ provided } s \text{ isn't free in } \varphi \quad (34)$$

4.2 The HYPE Fusion Operation

If we put aside, for the moment, the fact that the fusion function \circ in HYPE is a *partial* binary operation on *HypeStates* and instead take it to be a total fusion operation, then we can represent the HYPE \circ operation as the following *summation* operation (\oplus) on situations generally:

$$s \oplus s' =_{df} \iota s'' \forall p (s'' \models p \equiv (s \models p \vee s' \models p)) \quad (35)$$

In other words, $s \oplus s'$ is the situation that makes a proposition p true just in case either s makes p true or s' makes p true. Since $s \models p \vee s' \models p$ is modally collapsed, it follows that a proposition p is true in $s \oplus s'$ just in case either p is true in s or p is true in s' :

$$\vdash \forall p (s \oplus s' \models p \equiv (s \models p \vee s' \models p)) \quad (36)$$

To see that \oplus captures additional features about the partial nature of situations generally, let us say that s is a *part* of s' just in case every proposition true in s is true in s' :⁹

⁹The definition that follows was derived as a theorem in Zalta 1993 (412), as a consequence of the more general definition $x \leq y \equiv_{df} \forall F(xF \rightarrow yF)$ and the fact that situations encode only propositional properties. But for the present investigation, we may simply take the following as a definition.

$$s \sqsubseteq s' \equiv_{df} \forall p (s \models p \rightarrow s' \models p) \quad (37)$$

It follows relatively straightforwardly that s is a part of s' if and only if the sum of s and s' just is s' :

$$\vdash s \sqsubseteq s' \equiv s \oplus s' = s' \quad (38)$$

A further consequence of these definitions and theorems is that \oplus is idempotent, commutative, and associative with respect to situations *generally*. Since *HypeStates* are situations, it follows that:

$$\vdash \oplus \text{ is idempotent, commutative, and associative on } HypeStates. \quad (39)$$

Formally:

$$\begin{aligned} &\vdash s \oplus s \\ &\vdash s \oplus s' = s' \oplus s \\ &\vdash s \oplus (s' \oplus s'') = (s \oplus s') \oplus s'' \end{aligned}$$

Consequently, we may interpret $s \circ s'$ in Leitgeb 2019 as $s \oplus s'$.

Though $s \oplus s'$ is defined for *any* *HypeStates* s and s' , we could instead model the partiality of \circ in Leitgeb 2019 by introducing a partial ternary relation R^3 (not the ternary relation R of Routley-Meyer 1972, 1973) that may or may not relate a pair of *HypeStates* s and s' to a unique third *HypeState*.¹⁰ But we shall leave further details for some other occasion and continue with our total fusion operation \oplus .

4.3 The HYPE Explicit Incompatibility Relation

Next, we define HYPE's *explicit incompatibility* condition \perp in object-theoretic terms. First, we define the explicit incompatibility of situations generally. We say s is explicitly incompatible with s' just in case there is a proposition p such that s makes p true and s' makes the negation of p true:

¹⁰Intuitively, R would be a partial relation that is idempotent and commutative when $\iota s_0 R s s' s_0$ exists. Then we could re-define \circ for *HypeStates* so that it meets the following condition:

$$s \circ s' \equiv_{df} \iota s'' \forall p (s'' \models p \equiv s \models p \vee s' \models p \vee \iota s_0 (R s s' s_0) \models p)$$

The intuition here is that R ensures that $s \circ s'$ makes true *Hype*-propositions other than the ones true in s and s' . Moreover, we must also require:

$$\iota s_0 R s_1 ((s_1 \circ s_2) \circ s_3) s_0 \sqsubseteq (s_1 \circ s_2) \circ s_3$$

The extra constraint on R guarantees partial associativity. Thus, constraints on R validate idempotence, commutativity when defined, and partial associativity when defined.

$$s ! s' \equiv_{df} \exists p (s \models p \ \& \ s' \models \bar{p}) \quad (40)$$

Since explicit incompatibility is now defined for all situations, it is defined on *HypeStates*, i.e., we may henceforth write $s ! s'$ when *HypeStates* are explicitly incompatible.

Now the first principle governing \perp in HYPE is (Leitgeb 2019, 322):

- If there is a v with $v \in V(s)$ and $\bar{v} \in V(s')$, then $s \perp s'$.

Given our interpretation of \perp in terms of $!$, this becomes represented and derived as the following theorem governing *HypeStates* and *Hype*-propositions:

$$\vdash (s \models p \ \& \ s' \models \bar{p}) \rightarrow s ! s' \quad (41)$$

And the second principle governing \perp in HYPE is (Leitgeb 2019, 322):

- If $s \perp s'$ and both $s \circ s''$ and $s' \circ s'''$ are defined, then $s \circ s'' \perp s' \circ s'''$.

Given our interpretation of \circ as \oplus and the fact that $s \oplus s'$ is always defined for any situations s and s' , this becomes represented and derived as the following theorem regarding *HypeStates*:

$$\vdash s ! s' \rightarrow (s \oplus s'') ! (s' \oplus s''') \quad (42)$$

The proofs of both theorems are in the Appendix.

5 Routley Star in HYPE

We continue to use our restricted variables ' p ' and ' s ' to range over *Hype*-propositions and *HypeStates*, respectively. Our next goal, then, is to reconstruct and derive the principles that govern the HYPE Routley star operator. So the goal is to reconstruct and derive the following conditions laid down in Leitgeb 2019 (322), in which we've replaced Leitgeb's variable ' s ' by our restricted variable ' s ':

For every s in S ,

- (A) there is a unique $s^* \in S$ (the star image of s) such that:
- (B) $V(s^*) = \{\bar{v} \mid v \in V(s)\}$,
- (C) $s^{**} = s$,
- (D) s and s^* are not incompatible, i.e., $\neg(s \perp s^*)$, and

- (E) s^* is the largest state compatible with s , i.e., if s is not incompatible with s' , then the fusion of s' and s^* is defined and the fusion of $s' \circ s^* = s^*$.

Note that s^* is defined in HYPE as $V(s^*) = \{\bar{v} | v \notin V(s)\}$, instead of as $V(s^*) = \{v | \bar{v} \in V(s)\}$. However, as we saw in Section 3, these two definitions become equivalent if propositions and their double negations are generally identified. And as we saw in Section 4, Leitgeb does identify p and $\bar{\bar{p}}$ in his propositional language \mathcal{L} . Since we've defined *Hype*-propositions as ones that exhibit this behavior, let us examine how the HYPE Routley star and the principles governing it can be defined or derived given our analysis of *Hype*-propositions and *HypeStates*.

For any *HypeState* s , we may define the HYPE Routley star image of s , written s^* , as the *HypeState* s' that makes a *Hype*-proposition p true just in case p is the negation of a proposition not true in s :¹¹

$$s^* =_{df} \iota s' \forall p (s' \models p \equiv \exists q (\neg s \models q \ \& \ p = \bar{q})) \quad (43)$$

We take (43) to be a reconstruction of principle (B) above. Now although the HYPE principle (A) requires that there be a unique s^* satisfying (B) – (E), it should be clear that s^* is already uniquely defined; for any s , exactly one s^* has been identified by a canonical description.

So we may immediately conclude that s^* exists, for any s . Before we show that s 's unique star image s^* also satisfies constraints (C) – (E), it proves useful to first confirm a few facts that follow from (43).

By now familiar reasoning, we may infer that for any *Hype*-proposition p , p is true in s^* just in case p is the negation of a *Hype*-proposition that fails to be true in s :

$$\vdash \forall p (s^* \models p \equiv \exists q (\neg s \models q \ \& \ p = \bar{q})) \quad (44)$$

Moreover, we may verify that the principle proved in Section 3 holds for *HypeStates*, namely that p is the negation of some proposition that s fails to make true if and only if s fails to make \bar{p} true:

$$\vdash \exists q (\neg s \models q \ \& \ p = \bar{q}) \equiv \neg s \models \bar{p} \quad (45)$$

¹¹The following should be considered a *redefinition* of the Routley star image. That's because *HypeStates* are situations and, in Section 2, (14) defines the Routley star on situations. So to avoid conflicting definitions, just consider the following as a redefinition of this operator.

Clearly, then, (44) and (45) imply that s^* makes p true if and only if s fails to make \bar{p} true; and by simple logical consequence of this fact, it follows that \bar{p} is true in a *HypeState* s if and only if it is not the case that p is true in s^* :

$$\vdash \forall p (s^* \models p \equiv \neg s \models \bar{p}) \quad (46)$$

$$\vdash \forall p (s \models \bar{p} \equiv \neg s^* \models p) \quad (47)$$

(46) is a direct analogue of the Routley & Routley condition (iv) described in the Introduction above, and so corresponds directly to (15).

Note next that we can make use of the definitions of gaps and gluts in (17) and (18), respectively; these notions were defined generally for any situations and propositions and so apply to *HypeStates* and *Hype*-propositions. We may then further confirm that (43) is correct by establishing that if s has a glut w.r.t. p , then s^* has a gap w.r.t. p ; if s has a gap w.r.t. p , then s^* has a glut w.r.t. p ; and if s has neither a glut nor a gap w.r.t. p , then s^* agrees with s on p :

$$\vdash \text{GlutOn}(s, p) \rightarrow \text{GapOn}(s^*, p) \quad (48)$$

$$\vdash \text{GapOn}(s, p) \rightarrow \text{GlutOn}(s^*, p) \quad (49)$$

$$\vdash (\neg \text{GlutOn}(s, p) \ \& \ \neg \text{GapOn}(s, p)) \rightarrow (s^* \models p \equiv s \models p) \quad (50)$$

Now that we have confirmed that (43) is a definition of s^* that yields the latter's desired characteristics, we turn to the derivation of principle (C) governing HYPE s^* , namely, that s^{**} is identical to s :

$$\vdash s^{**} = s \quad (51)$$

Cf. Leitgeb 2019 (322). So, whereas (28) establishes that the stipulation $s^{**} = s$ in Routley & Routley 1973 is equivalent to the double-negation condition $\forall p (s \models p \equiv s \models \bar{\bar{p}})$, (22) establishes that the analogous stipulation $s^{**} = s$ in Leitgeb 2019 can be derived from the double-negation fact that $\forall p (p = \bar{\bar{p}})$. These results give us a deeper understanding of the connection between the two ways of defining the Routley star image of a situation.

Principles (D) and (E) of HYPE s^* may be derived as follows. (D) asserts that s is not explicitly incompatible with s^* :

$$\vdash \neg s!s^* \quad (52)$$

And since $s' \oplus s^*$ is always defined in our reconstruction, we can reconstruct and derive (E) as the simpler claim if s is not incompatible with s' , then the sum/fusion of s' and s^* just is s^* :

$$\vdash \neg s!s' \rightarrow (s' \oplus s^* = s^*) \quad (53)$$

(53) guarantees that s^* is the largest state compatible with s .

Finally, if we recall the definition $s \leq s'$ (37) and the fact that $s \leq s' \equiv \forall p(s \models p \rightarrow s' \models p)$ (38), we may prove that the Routley star operation reverses \leq :

$$\vdash s \leq s' \rightarrow s'^* \leq s^* \quad (54)$$

Cf. Observation 3, Leitgeb 2019 (325). This completes the derivation of the principles stipulated in HYPE for the Routley star operation, modulo the partiality of the HYPE fusion operation.

6 Conclusion

We've now answered the question: What kind of metaphysics is represented by a semantics making use of Routley star? Without assuming any mathematical entities or theory of sets and functions, we've used OT to define two forms of the Routley star operation and derive the principles that govern these forms. And the better we understand the theorems that are implied by the two ways of defining it, the better we understand how the star operation might be used. The existence of the Routley star image s^* of a situation s is guaranteed not by set theory but by a theory of abstract objects. And our reconstruction shows that situations have both a metaphysical character and an informational character, at least as these are described in the quote above from Leitgeb 2019 (footnote 9). One can view situations in OT as “chunks of reality” that are “located in the world”, especially if one takes an Aristotelian view of abstract objects as forms that are part of reality. Alternatively, one can view situations informationally, as abstract entities corresponding to “pieces of thought”. But these metaphilosophical considerations about how to interpret OT as a theory shouldn't divert attention away from the tight conceptual framework that OT provides for defining Routley star.

Indeed, if you look at how situations and the Routley star operation are defined in (1), (14), and (43) within this conceptual framework, one might even suggest that the star operation is a logical one. Propositions

are axiomatized as 0-ary relations and can be considered part of logic. Situations are defined in (1) as abstract objects that encode only propositional properties. And the $*$ operation is then defined on situations in terms of the notions *the, truth in* (which is in turn defined in terms of the *encoding* mode of predication), *every* and *some, if and only if*, and *not*. If the star operation is logical, then we can explain why some have thought that it helps us to capture semantically a more general and flexible logical concept of negation.¹²

Finally, we've shown that the basic principles governing Routley star need not be stipulated but can be derived from its definition. This integrates Routley star into a more general theory of (partial) situations that has been shown, in previous work, to ground the theory of both possible worlds and impossible worlds. This analysis of the Routley star operation clarifies our understanding of the Routley-Meyer ternary relation R (Routley-Meyer 1972, 1973) on ‘set-ups’, by systematically validating many of the assumptions of situation theory used in Mares' (2004) motivation and justification for R .

Appendix: Proofs of the Theorems

(7)¹³ If we eliminate the restricted variable, then the theorem we have to prove becomes:

$$\exists x(\text{Situation}(x) \ \& \ \forall p(x \models p \equiv \varphi)), \text{ provided } x \text{ isn't free in } \varphi$$

So let φ be any formula in which x doesn't occur free. (Note that the variable p may or may not be free in φ .) Now, pick a property variable that doesn't occur free in φ . Without loss of generality, suppose it is G . Then let ψ be the formula $\exists p(\varphi \ \& \ G = [\lambda z p])$. Clearly, since x doesn't occur free in ψ , and so the following is a schematic instance of (an alphabetic variant of) the comprehension principle for abstract objects formally stated in footnote 3:

$$\exists x(A!x \ \& \ \forall G(xG \equiv \psi))$$

But given our choice of ψ , this amounts to:

$$\exists x(A!x \ \& \ \forall G(xG \equiv \exists p(\varphi \ \& \ G = [\lambda z p])))$$

¹²I'm indebted to Hannes Leitgeb for suggesting this point.

¹³I'm indebted to Uri Nodelman for spotting a flaw in the original proof of this theorem.

Let a be such an object, so that we know both $A!a$ and:

$$(A) \quad \forall G(aG \equiv \exists p(\varphi \& G=[\lambda z p]))$$

It follow *a fortiori* that $\forall G(aG \rightarrow \exists p(G=[\lambda z p]))$. Hence $Situation(a)$, by definition (1). So it remains to show $\forall p(a \models p \equiv \varphi)$. By GEN, it suffices to show $a \models p \equiv \varphi$, since we've made no special assumptions about p .

To prove this biconditional, we'll rely on the fact that $a \models p$ is defined as $a[\lambda z p]$, by (2), given that a is a situation. We'll therefore want to instantiate $a[\lambda z p]$ into (A). But there is a clash of variables and, to avoid this, we use the following alphabetic variant of (A), where q is a variable that is substitutable for p , and doesn't occur free, in φ :

$$(A') \quad \forall G(aG \equiv \exists q(\varphi_p^q \& G=[\lambda z q]))$$

Now we can properly instantiate $[\lambda z p]$ into (θ') , and if we remember that G doesn't occur free in φ , we obtain:¹⁴

$$(B) \quad a[\lambda z p] \equiv \exists q(\varphi_p^q \& [\lambda z p]=[\lambda z q])$$

With these facts we can prove $a \models p \equiv \varphi$.

(\rightarrow) Assume $a \models p$, to show φ . Then $a[\lambda z p]$, by (2). So by (B), it follows that:

$$\exists q(\varphi_p^q \& [\lambda z p]=[\lambda z q])$$

Now suppose q_1 is such a proposition, so that we know:

$$(C) \quad (\varphi_p^q)_{q_1}^{q_1} \& [\lambda z p]=[\lambda z q_1]$$

In OT, propositions are identical whenever the propositional properties constructed from them are identical (Zalta 1993, 409). So by the second conjunct of (C), it follows that $p = q_1$. Hence, by the first conjunct of (C), it follows that $(\varphi_p^q)_q^p$. But since the conditions of the Re-replacement Lemma are met (Enderton 2001, 130), this latter is just φ .

(\leftarrow) Assume φ . Then $\varphi \& [\lambda z p]=[\lambda z p]$, by the reflexivity of identity. Hence, by existential introduction:

$$\exists q(\varphi_p^q \& [\lambda z p]=[\lambda z q])$$

¹⁴Strictly speaking, when we instantiate $[\lambda z p]$ into (A') , we obtain:

$$a[\lambda z p] \equiv \exists q((\varphi_p^q)_G^{[\lambda z p]} \& [\lambda z p]=[\lambda z q])$$

But since G isn't free in φ , $(\varphi_p^q)_G^{[\lambda z p]}$ is just φ_p^q .

Then by (B), $a[\lambda z p]$. So by (2) and the fact that a is a situation, $a \models p$. \bowtie

(8) This is Theorem 2 in Zalta 1993. The proof was given in Zalta 1991 (Appendix A), which served as a precursor to Zalta 1993.

(9) This follows from (7) and (8) by the standard definition of the uniqueness quantifier $\exists!s\psi$.

(11) Suppose y is substitutable for x in φ and assume $y = ix\varphi$. Then by axiom (10), $\forall x(\mathcal{A}\varphi \equiv x = y)$. But since y is substitutable for x in φ , we can instantiate this last fact to y and we obtain $\mathcal{A}\varphi_x^y \equiv y = y$. So by the reflexivity of identity, $\mathcal{A}\varphi_x^y$. \bowtie

(12) By hypothesis, φ is modally collapsed and y is substitutable for x in φ . Now assume $y = ix\varphi$, to show φ_x^y . It follows from this assumption by theorem (11) that $\mathcal{A}\varphi_x^y$. But since φ is modally collapsed, there is a proof of $\Box(\varphi \rightarrow \Box\varphi)$. Since this latter is a theorem, it follows by GEN that $\forall x\Box(\varphi \rightarrow \Box\varphi)$. Instantiating to y it follows that $\Box(\varphi_x^y \rightarrow \Box\varphi_x^y)$. But as we saw in footnote 5, a formula of this form implies $\mathcal{A}\varphi_x^y \equiv \varphi_x^y$. Hence, φ_x^y . \bowtie

(13) Suppose s' isn't free in φ and φ is modally collapsed. To show:

$$(s = is'\forall p(s' \models p \equiv \varphi)) \rightarrow \forall p(s \models p \equiv \varphi)$$

it suffices to show that the formula $\forall p(s' \models p \equiv \varphi)$ is modally collapsed, for then our theorem becomes an instance of (12). So we have to prove:

$$\Box(\forall p(s' \models p \equiv \varphi) \rightarrow \Box\forall p(s' \models p \equiv \varphi))$$

By the Rule of Necessitation, it suffices to prove:

$$\forall p(s' \models p \equiv \varphi) \rightarrow \Box\forall p(s' \models p \equiv \varphi)$$

So assume $\forall p(s' \models p \equiv \varphi)$, to show $\Box\forall p(s' \models p \equiv \varphi)$. By the Barcan Formula, it suffices to show $\forall p\Box(s' \models p \equiv \varphi)$. Since p isn't free in our assumption, it remains, by GEN, to show $\Box(s' \models p \equiv \varphi)$. So p is a fixed, but arbitrary proposition, and so our assumption that $\forall p(s' \models p \equiv \varphi)$ implies:

$$(A) \quad s' \models p \equiv \varphi$$

By hypothesis, φ is modally collapsed, and so we know that the following is a theorem:

$$(B) \quad \Box(\varphi \rightarrow \Box\varphi)$$

But independently, note that $s' \models p$ is defined in (2) as $s'[\lambda yp]$, and so it is a formula of the form xF . Since the modal logic of encoding is expressed by the principle $xF \rightarrow \Box xF$ (Zalta 1993, 403), it follows by the Rule of Necessitation that $\Box(xF \rightarrow \Box xF)$. Hence as an instance, we know:

$$(C) \quad \Box(s' \models p \rightarrow \Box s' \models p)$$

But it is a theorem of modal logic that if formulas ψ and χ necessarily imply their own necessity, then the material equivalence of ψ and χ necessarily implies their necessary equivalence:

$$(\Box(\psi \rightarrow \Box\psi) \& \Box(\chi \rightarrow \Box\chi)) \rightarrow \Box((\psi \equiv \chi) \rightarrow \Box(\psi \equiv \chi))$$

Given this theorem and setting ψ to $s \models p$ and χ to φ , (C) and (B) jointly imply:

$$\Box((s' \models p \equiv \varphi) \rightarrow \Box(s' \models p \equiv \varphi))$$

So by the T schema,

$$(s' \models p \equiv \varphi) \rightarrow \Box(s' \models p \equiv \varphi)$$

Hence, by (A), $\Box(s' \models p \equiv \varphi)$, which is what it remained to show. \bowtie

(15) First, we show that $\neg s \models \bar{p}$ is a modally collapsed formula:

$$\text{Lemma: } \Box(\neg s \models \bar{p} \rightarrow \Box \neg s \models \bar{p})$$

Proof. By the Rule of Necessitation, it suffices to prove $\neg s \models \bar{p} \rightarrow \Box \neg s \models \bar{p}$. So assume $\neg s \models \bar{p}$, to show $\Box \neg s \models \bar{p}$. Now, as previously noted in the text, the modal logic of encoding is $xF \rightarrow \Box xF$. So, by the T schema and the Rule of Necessitation, we know $\Box(xF \equiv \Box xF)$. This implies $\Box(\Diamond xF \equiv xF)$. As an instance of this latter, $\Box(\Diamond s \models \bar{p} \equiv s \models \bar{p})$. Then by the T schema, $\Diamond s \models \bar{p} \equiv s \models \bar{p}$. So, negating both sides, $\neg \Diamond s \models \bar{p} \equiv \neg s \models \bar{p}$. Then by our assumption, it follows that $\neg \Diamond s \models \bar{p}$, which is equivalent to $\Box \neg s \models \bar{p}$, which is what we had to show.

Now note that we can apply GEN to (13), since s is a free variable, to conclude:

$$\begin{aligned} &\forall s(s = \iota s' \forall p(s' \models p \equiv \varphi)) \rightarrow \forall p(s \models p \equiv \varphi), \\ &\text{provided } s' \text{ isn't free in } \varphi \text{ and } \varphi \text{ is modally collapsed} \end{aligned}$$

Now since s' isn't free in $\neg s \models \bar{p}$ and this formula is modally collapsed, we can let φ be $\neg s \models \bar{p}$, so that as an instance of the foregoing, we know:

$$\forall s(s = \iota s' \forall p(s' \models p \equiv \varphi)) \rightarrow \forall p(s \models p \equiv \neg s \models \bar{p})$$

So we may instantiate s^* into this universal claim and the result is:

$$s^* = \iota s' \forall p(s' \models p \equiv \neg s \models \bar{p}) \rightarrow \forall p(s^* \models p \equiv \neg s \models \bar{p})$$

So by definition (14), $\forall p(s^* \models p \equiv \neg s \models \bar{p})$. \bowtie

(16) By (15) we know:

$$(A) \quad \forall p(s^* \models p \equiv \neg s \models \bar{p})$$

Since $\varphi \equiv \neg \psi$ is necessarily equivalent to $\neg \varphi \equiv \psi$, it follows from (A) by the Rule of Substitution that:

$$(B) \quad \forall p(\neg s^* \models p \equiv s \models \bar{p})$$

And since $\varphi \equiv \psi$ is necessarily equivalent to $\psi \equiv \varphi$, it follows from (B) by the Rule of Substitution that:

$$\forall p(s \models \bar{p} \equiv \neg s^* \models p) \quad \bowtie$$

(19) Take the following as a global assumption:

$$(A) \quad s = s^{**}$$

We want to prove that if $GlutOn(s, p)$, then $GapOn(s^*, p)$. So assume $GlutOn(s, p)$, i.e., by (17), that:

$$(B) \quad s \models p \& s \models \bar{p}$$

To show $GapOn(s^*, p)$, we have to show both (a) $\neg s^* \models p$ and (b) $\neg s^* \models \bar{p}$, by (18).

(a) If we instantiate (16) to s and p , we obtain:

$$s \models \bar{p} \equiv \neg s^* \models p$$

So by the 2nd conjunct of (B), $\neg s^* \models p$.

(b) If we instantiate (16) to s^* and p , we obtain:

$$(C) \quad s^* \models \bar{p} \equiv \neg s^{**} \models p$$

But the 1st conjunct of (B) implies, under our global assumption $s = s^{**}$ (A), that $s^{**} \models p$. But this fact and (C) jointly imply $\neg s^* \models \bar{p}$. \bowtie

(20) Take the following as a global assumption:

$$(A) \quad s = s^{**}$$

We want to prove that if $GapOn(s, p)$, then $GlutOn(s^*, p)$. So assume $GapOn(s, p)$, i.e., by (18), that:

$$(B) \quad \neg s \models p \ \& \ \neg s \models \bar{p}$$

Then to show $GlutOn(s^*, p)$, we show both (a) $s^* \models p$ and (b) $s^* \models \bar{p}$, by (17).

(a) If we instantiate (15) to s and p , we obtain:

$$s^* \models p \equiv \neg s \models \bar{p}$$

This result and the second conjunct of (B) imply $s^* \models p$.

(b) If we instantiate (16) to s^* and p , we obtain:

$$(C) \quad s^* \models \bar{p} \equiv \neg s^{**} \models p$$

But given our global assumption (A) that $s = s^{**}$, it follows from the first conjunct of (B) that $\neg s^{**} \models p$. But from this fact and (C), it follows that $s^* \models \bar{p}$. \bowtie

(21) Assume both $\neg GlutOn(s, p)$ and $\neg GapOn(s, p)$. Then by definitions (17) and (18), we know:

$$\neg(s \models p \ \& \ s \models \bar{p})$$

$$\neg(\neg s \models p \ \& \ \neg s \models \bar{p})$$

These are, respectively, equivalent to:

$$(A) \quad \neg s \models p \vee \neg s \models \bar{p}$$

$$(B) \quad s \models p \vee s \models \bar{p}$$

We may then prove both directions of $s^* \models p \equiv s \models p$. (\rightarrow) Assume $s^* \models p$. Then by (15), $\neg s \models \bar{p}$. It follows from this and (B) that $s \models p$. (\leftarrow) Assume $s \models p$. This and (A) imply $\neg s \models \bar{p}$. So by (15), $s^* \models p$. \bowtie

(22) Assume:

$$\forall p(\neg GlutOn(s, p) \ \& \ \neg GapOn(s, p))$$

To show $s^* = s$, we have to show $\forall p(s^* \models p \equiv \neg s \models \bar{p})$, by (8). By GEN, we show $s^* \models p \equiv s \models p$. But if we instantiate our assumption to p , we obtain $\neg GlutOn(s, p) \ \& \ \neg GapOn(s, p)$, and so $s^* \models p \equiv s \models p$ follows by (21). \bowtie

(23) (\rightarrow) Our (global) assumption is:

$$\forall p(\neg GlutOn(s, p) \ \& \ \neg GapOn(s, p))$$

We want to show $\forall p(s \models p \equiv \neg s \models \bar{p})$. By GEN, it suffices to show $s \models p \equiv \neg s \models \bar{p}$. But it is an immediate consequence of our global assumption that:

$$(A) \quad \neg GlutOn(s, p) \ \& \ \neg GapOn(s, p)$$

We use this to prove both directions of our biconditional:

(\rightarrow) Assume (locally) $s \models p$. The first conjunct of (A) and definition (17) imply $\neg(s \models p \ \& \ s \models \bar{p})$, i.e., $\neg s \models p \vee \neg s \models \bar{p}$. This last fact and our local assumption jointly imply $\neg s \models \bar{p}$.

(\leftarrow) Assume (locally) $\neg s \models \bar{p}$. The second conjunct of (A) and definition (18) imply $\neg(\neg s \models p \ \& \ \neg s \models \bar{p})$, i.e., $s \models p \vee s \models \bar{p}$. But his last fact and our local assumption jointly imply $s \models p$.

(\leftarrow) Our (global) assumption is:

$$\forall p(s \models p \equiv \neg s \models \bar{p})$$

To show $\forall p(\neg GlutOn(s, p) \ \& \ \neg GapOn(s, p))$, it suffices by &I and GEN and to show both (a) $\neg GlutOn(s, p)$ and (b) $\neg GapOn(s, p)$. But it is an immediate consequence of our global assumption that:

$$(B) \quad s \models p \equiv \neg s \models \bar{p}$$

We use this to show both directions of our biconditional:

(\rightarrow) Assume, for reductio, that $GlutOn(s, p)$. Then by definition (17), we know both $s \models p$ and $s \models \bar{p}$. But the former implies the negation of the latter, by (B). Contradiction.

(\leftarrow) Assume, for reductio, that $GapOn(s, p)$. Then by (18), we know both $\neg s \models p$ and $\neg s \models \bar{p}$. But again, the former implies the negation of the latter, by (B). Contradiction. \bowtie

(26) Take as our global assumption that $\forall s(s^{**} = s)$. From definition (24) and the fact that the condition $p \neq p$ is modally collapsed (by the necessity of identity), it follows that $\forall p(s_0 \models p \equiv p \neq p)$, by (13). But since no proposition fails to be self-identical, it follows from this last fact that $\neg \exists p(s_0 \models p)$. This implies $\forall p \neg(s_0 \models p)$. Now let q be an arbitrarily chosen proposition, so that we know both $\neg s_0 \models q$ and $\neg s_0 \models \bar{q}$. Then by definition (18), $GapOn(s_0, q)$. But given our global assumption, we know $s_0^{**} = s_0$. So by the relevant instance of (20), it follows from $GapOn(s_0, q)$ that $GlutOn(s_0^*, q)$. From this, it follows *a fortiori* by definition (17) that $s_0^* \models q$. Since q was arbitrary, we have established:

$$(A) \quad \forall p(s_0^* \models p)$$

But, independently, we also know, given definition (25) and the fact that the condition $p = p$ is modally collapsed (by the necessity of identity), that $\forall p(s_V \models p \equiv p = p)$. Since every proposition is self-identical, it follows from this last fact that:

$$(B) \quad \forall p(s_V \models p)$$

Now $\forall p \phi \wedge \forall p \psi$ implies $\forall p(\phi \equiv \psi)$. So we may conclude from (A) and (B) that:

$$\forall p(s_0^* \models p \equiv s_V \models p)$$

Since s_0^* and s_V are situations that make the same propositions true, it follows by (8) that $s_0^* = s_V$. \bowtie

(27) (Exercise)

(28) (\rightarrow) Assume $s^{**} = s$. By GEN, it suffices to show $s \models p \equiv s \models \bar{\bar{p}}$. The identity of s^{**} and s implies, by (8), that $\forall p(s^{**} \models p \equiv s \models p)$. Hence $s^{**} \models p \equiv s \models p$, which commutes to:

$$(A) \quad s \models p \equiv s^{**} \models p$$

Now, independently, if we instantiate (15) to s^* and p , we also know:

$$(B) \quad s^{**} \models p \equiv \neg s^* \models \bar{p}$$

Moreover, independently, we know $s^* \models \bar{p} \equiv \neg s \models \bar{\bar{p}}$, by instantiating (15) to s and \bar{p} . By negating both sides and eliminating the double negation, we have:

$$(C) \quad \neg s^* \models \bar{p} \equiv s \models \bar{\bar{p}}$$

So $s \models p \equiv s \models \bar{\bar{p}}$, by biconditional syllogism from (A), (B), and (C).

(\leftarrow) Assume:

$$(D) \quad \forall p(s \models p \equiv s \models \bar{\bar{p}})$$

To establish $s^{**} = s$, we appeal to (8) and show $\forall p(s^{**} \models p \equiv s \models p)$. By GEN, it suffices to show $s^{**} \models p \equiv s \models p$. First note that, by GEN, (15) holds for all s and so if we instantiate the resulting universal claim to s^* and p , we obtain:

$$(E) \quad s^{**} \models p \equiv \neg s^* \models \bar{p}$$

Independently, we obtain $s^* \models \bar{p} \equiv \neg s \models \bar{\bar{p}}$ by instantiating (15) to s and \bar{p} . This is equivalent to:

$$(F) \quad \neg s^* \models \bar{p} \equiv s \models \bar{\bar{p}}$$

Moreover, if instantiate (D) to p and commute the result, we know:

$$(G) \quad s \models \bar{\bar{p}} \equiv s \models p$$

But now, (E), (F), and (G) jointly imply:

$$s^{**} \models p \equiv s \models p \quad \bowtie$$

(30) Assume $Hype(p)$. Then by (29), $p = \bar{\bar{p}}$. So we may substitute $\bar{\bar{p}}$ for the first occurrence of p in the identity $\bar{p} = \bar{p}$, to obtain $\bar{\bar{p}} = \bar{p}$. So by definition (29), $Hype(\bar{p})$. \bowtie

(33) By reasoning analogous to (7).

(34) By (33) and the definition of identity for situations (8).

(36) This is a consequence of (35) and (13), and the fact that $s \models p \vee s' \models p$ is modally collapsed. \bowtie

(38) We prove both directions.

(\rightarrow) Assume $s \leq s'$. It follows that $\forall p(s \models p \rightarrow s' \models p)$, by definition (37). Now to show $s \oplus s' = s'$, we have to show that $s \oplus s'$ and s' make the same propositions true, by (8). That is, we have to show, for an arbitrary p , that $s \oplus s' \models p \equiv s' \models p$. But both directions of this biconditional hold. If $s \oplus s' \models p$ then either $s \models p$ or $s' \models p$, by (36). But in either case, $s' \models p$,

given that every proposition true in s is true in s' . And if $s' \models p$, then clearly, by a fact about \oplus (36), it follows that $s \oplus s' \models p$.

(\leftarrow) Assume $s \oplus s' = s'$. It follows by (8) that $s \oplus s'$ and s' make the same propositions true. Now to show $s \leq s'$, we need to show, for an arbitrary proposition p , that $s \models p \rightarrow s' \models p$. So assume $s \models p$, to show $s' \models p$. But since $s \oplus s'$ and s' make the same propositions true, it suffices to show $s \oplus s' \models p$. But this follows from our assumption that $s \models p$, by (36). \bowtie

(39) The idempotence, commutativity, and associativity of \oplus with respect to situations and, *a fortiori*, *HypeStates*, follows from (36) and the facts that \vee is idempotent, commutative, and associative. \bowtie

(41) This follows from the definition of $s!s'$ (40) once it is instantiated when to *HypeStates* s and s' .

(42) Assume $s!s'$. Then by definition (40), we know $\exists p(s \models p \ \& \ s' \models \bar{p})$. Suppose p_1 is such a proposition, so that we know $s \models p_1$ and $s' \models \bar{p}_1$. But since $s \models p_1$, so does $s \oplus s''$, by theorem (36). And by that same theorem, since $s' \models \bar{p}_1$, so does $s' \oplus s'''$. Hence:

$$\exists p((s \oplus s'' \models p) \ \& \ (s' \oplus s''' \models \bar{p}))$$

So by definition (40), $(s \oplus s'')!(s' \oplus s''')$. \bowtie

(44) (Exercise)

(45) By reasoning analogous to the proof of (ω) in Section 3, though stated in terms of *Hype*-propositions and *HypeStates*. \bowtie

(46) This follows from (44) by (45) and the Rule of Substitution. \bowtie

(47) (Exercise)

(48) Assume $GlutOn(s, p)$, i.e., by (17) that:

$$(A) \ s \models p$$

$$(B) \ s \models \bar{p}$$

We want to show $GapOn(s^*, p)$, i.e., by (18), that both (a) $\neg s^* \models p$ and (b) $\neg s^* \models \bar{p}$. (a) This follows from (B) by (47). (b) If we instantiate (46) to \bar{p} , we have $s^* \models \bar{p} \equiv \neg s \models \bar{\bar{p}}$. But this is equivalent to $\neg s^* \models \bar{p} \equiv s \models \bar{\bar{p}}$. Since *Hype*-propositions are identical to their double-negations (29), it follows that $\neg s^* \models \bar{p} \equiv s \models p$. Then by (A), we may infer $\neg s^* \models \bar{p}$. \bowtie

(49) Assume $GapOn(s, p)$, i.e., by (18):

$$(A) \ \neg s \models p$$

$$(B) \ \neg s \models \bar{p}$$

We want to show $GlutOn(s^*, p)$, i.e., by (17), that both (a) $s^* \models p$ and (b) $s^* \models \bar{p}$. (a) This follows from (B) by (46). (b) If we instantiate (46) to \bar{p} , we have $s^* \models \bar{p} \equiv \neg s \models \bar{\bar{p}}$. Since *Hype*-propositions are identical to their double-negations (29), it follows that $s^* \models \bar{p} \equiv \neg s \models p$. From this and (A) it follows that $s^* \models \bar{p}$. \bowtie

(50) This follows by applying the reasoning in (21) to *HypeStates* and *Hype*-propositions. \bowtie

(51) To establish $s^{**} = s$, we note that since *HypeStates* encode only *Hype*-propositions (32), it suffices by (8) to show $\forall p(s^{**} \models p \equiv s \models p)$. By GEN, it then suffices to show $s^{**} \models p \equiv s \models p$. Now if we instantiate (46) to s^* , we obtain:

$$(A) \ s^{**} \models p \equiv \neg s^* \models \bar{p}$$

Independently, if instantiate (47) to \bar{p} , we obtain $s \models \bar{\bar{p}} \equiv \neg s^* \models \bar{p}$, which by the commutativity of the biconditional, implies:

$$\neg s^* \models \bar{p} \equiv s \models \bar{\bar{p}}$$

And since *Hype*-propositions are identical with their double negations, it follows from this last result that:

$$(B) \ \neg s^* \models \bar{p} \equiv s \models p$$

But (A) and (B) imply $s^{**} \models p \equiv s \models p$. \bowtie

(52) Assume, for reductio, that $s!s^*$. So by definition (40), $\exists p(s \models p \ \& \ s^* \models \bar{p})$. Let q_1 be such a proposition, so that we know $s \models q_1$ and $s^* \models \bar{q}_1$. By a key fact about s^* (46), the latter implies $\neg s \models \bar{\bar{q}}_1$. But since *Hype*-propositions are identical with their double negations, it follows that $\neg s \models q_1$. Contradiction. \bowtie

(53) Assume $\neg s!s'$. So by definition (40):

$$(A) \ \neg \exists p(s \models p \ \& \ s' \models \bar{p})$$

We want to show $s' \oplus s^* = s^*$. By (8) and the fact that *HypeStates* encode only *Hype*-propositions (32), it suffices to show that $\forall p((s' \oplus s^*) \models p \equiv s^* \models p)$. So, by GEN, we show $(s' \oplus s^*) \models p \equiv s^* \models p$.

(\rightarrow) Assume $(s' \oplus s^*) \models p$. Independently, by (36), we know:

$$\forall p((s' \oplus s^*) \models p \equiv s' \models p \vee s^* \models p)$$

Hence, $s' \models p \vee s^* \models p$. Assume, for reductio, that $\neg s^* \models p$. Then $s' \models p$, and since *Hype*-propositions are identical to their double negations (29), we know $s' \models \bar{p}$. But it also follows from our reductio assumption, by (47), that $s \models \bar{p}$. So we've established $s \models \bar{p}$ & $s' \models \bar{p}$. Existentially generalizing on \bar{p} , it follows that $\exists q(s \models q \& s' \models \bar{q})$, which contradicts (A).

(\leftarrow) Exercise. \bowtie

(54) Assume $s \trianglelefteq s'$. Since theorem (38) holds for any situations, it holds for *HypeStates*. So it follows that:

$$(A) \quad s \oplus s' = s'$$

Now independently, by (52), we know that s' is not incompatible with its Routley star image s'^* , i.e., $\neg s'!s'^*$. From this and (A), it follows that the fusion of s and s' is not incompatible with with the Routley star image of s' , i.e., that:

$$(B) \quad \neg(s \oplus s')!s'^*$$

Now consider the following Lemma, which holds for any situations s , s' , and s'' :

$$\text{Lemma: } \neg(s \oplus s')!s'' \rightarrow \neg s!s''$$

Proof: Assume $\neg(s \oplus s')!s''$. Then by definition of ! (40), we know $\neg \exists p((s \oplus s') \models p \& s'' \models \bar{p})$. Now suppose, for reductio, that $s!s''$. Then $\exists p(s \models p \& s'' \models \bar{p})$. Suppose q_1 is such a proposition, so that we know both $s \models q_1$ and $s'' \models \bar{q}_1$. But the former implies $s \oplus s' \models q_1$, by definition of $s \oplus s'$ (35). So we know $(s \oplus s') \models q_1 \& s'' \models \bar{q}_1$. Hence, $\exists p((s \oplus s') \models p \& s'' \models \bar{p})$. Contradiction.

Given this Lemma, it follows from (B) that s is not incompatible with s'^* , i.e., $\neg s!s'^*$. But by (53), this last result implies $s'^* \oplus s^* = s^*$. Hence, by (38), $s'^* \trianglelefteq s^*$. \bowtie
